THE PATENTS ACT 1990

PROVISIONAL SPECIFICATION FOR THE INVENTION ENTITLED

"AN ATTACHMENT SYSTEM"

The present invention will be described in the following statement:

The present invention relates to an attachment system, particularly intended for the attachment of ground engaging tools to the lip plate of mechanical digging devices.

5 Many mining and earthmoving operations require the use of mechanical digging devices, such as front-end loaders. Such mechanical digging devices commonly feature buckets which can be manipulated by a user to dig into earth or rocks to be shifted. These buckets include a lip plate across the bucket floor. On this lip are mounted a series of ground engaging tools having a tooth-like appearance. These tools, in use, penetrate into the material being dug, and provide a leading edge for the
10 bucket to follow.

The ground engaging tools are highly susceptible to wear due to the high level of friction generated by their use. Accordingly, it is often desirable to be able to remove a worn ground engaging tool and substitute a new tool.

A common method of attachment for ground engaging tools is that of welding. In
15 practice, however, a welded ground engaging tool can be difficult to replace without substantial dismantling of the bucket.

Mechanical methods of attaching ground engaging tools through the use of restraining bolts and pins have been proposed. These methods are often difficult to use in practice, as the forces generated against a ground engaging tool can cause
20 deformation of the bolt or pin, thus making subsequent disengagement difficult.

The present invention attempts to overcome at least in part some of the aforementioned disadvantages of previous attachment system for ground engaging tools.

In accordance with one aspect of the present invention there is provided an attachment system for connecting a first member to a second member, characterised in that the first member has a lug connected thereto, and the second member has an aperture arranged, in use, about the lug, the aperture including a slot arranged to receive a stabilizing member, and wherein a clamping member is disposed between the lug and the stabilizing member such that the supply of pressure to the clamping member acts to restrain disengagement of the second member from the lug.

The present invention will now be described, by way of example, with reference to the accompanying drawings, in which:

Figure 1 is a perspective view of a ground engaging tool arranged to be attached to a lip plate (a portion of which is shown) in accordance with the present invention;

Figure 2 is perspective view of the underside of the ground engaging tool of Figure 1;

Figure 3 is a perspective view of the ground engaging tool and lip plate portion of Figure 1, shown during attachment, together with a clamping member in accordance with the present invention; and

Figures 4 to 8 are sequential cross sectional views of a portion of the ground engaging tool and lip plate of Figures 1 to 3 during the attachment process.

Referring to the Figures, there is shown a ground engaging tool 10 arranged to be attached to a portion of a lip plate 12. The lip plate 12 is substantially rectangular in cross section, and extends around the rim of a bucket (not shown) of a mechanical digging device. The lip plate 12 includes an upper face 14, a lower face 16 and an end

face 18. A tapered surface 20 extends from the end face 18 of the lip plate 12 to the upper face 14.

The lip plate 12 includes a lug 22 affixed by suitable means to the upper face 14. In the embodiment shown in the drawings the lug 22 is affixed by a weld 31. The lug 22 is oriented towards the end face 18 of the lip plate 12, and includes a top surface 26 which curves upwardly in a convex fashion from a first end of the lug 22 adjacent the tapered surface 20 to a second end of the lug 22 remote from the tapered surface 20. The lug 22 further includes a substantially flat rear face 30 at the second end of the lug 22, the rear face 30 extending from the top surface 26 to the upper face 14, and being substantially perpendicular to the upper face 14 and parallel to the end face 18. The lug 22 has a side wall 24 which extends about the lug 22 and is bordered by the upper face 14, the top surface 26 and the rear face 30.

The ground engaging tool 10 comprises a leading edge 32, a first base portion 34 extending substantially perpendicularly of the leading edge 32, a front portion 36 extending away from the leading edge at a shallow angle, a second base portion 38 extending away from the first base portion 34 at a shallow angle, a transverse recess 40 disposed oppositely the leading edge 32 and an attachment portion 42. The front portion 36, leading edge 32 and the first base portion 34 co-operate to form a substantially V shaped working portion in order to penetrate, in use, the material being dug. The transverse recess 40 is complementary in shape to the lip plate 12, and allows the ground engaging tool 10 to be located on the perimeter of the lip plate 12 adjacent the end face 18. The second base portion 38 tapers from the first base portion 34 in a direction away from the leading edge 32, and ends, in use, adjacent the lip plate 12.

The attachment portion 42 extends from the front portion 36 adjacent the recess 40 in a direction away from the leading edge 32. It locates, in use, along the upper face 14 of the lip plate 12, and co-operates with the lug 22.

The attachment portion 42 has a substantially flat lower surface 44, a substantially flat upper surface 46 and a rear surface 48. The attachment portion 42 includes an engaging recess 50 extending inwardly of the rear surface 48 through a rear aperture 52 in the rear surface 48, and upwardly of the lower surface 44 through a lower aperture 45. The engaging recess 50 has a first portion 54 remote from the rear aperture 52, and a second portion 56 adjacent the rear aperture 52. The first portion 54 is complementary in shape to the lug 22, whereas the second portion 56 has substantially constant cross section. The second portion 56 is in the shape of a chamfered rectangle in cross section, and is slightly larger in dimension than the rear face 30 of the lug 22. This allows, in use, the second portion 56 to be placed about the lug 22. This in turn allows the attachment portion 42 to be slid over the lug 22 in a longitudinal direction, and to locate in a position whereby the lug 22 is within the first portion 54 of the engaging recess 50. In this position relative movement of the attachment portion 42 and the lip plate 12 in a transverse direction is restricted.

The attachment portion 42 further includes a rectangular slot 57 which extends from an aperture 58 within the upper surface 46 to the lower surface 44. The rectangular slot 57 is arranged in a transverse direction, and is located within the second portion 56 of the engaging recess 50. The rectangular slot 57 is larger in the transverse direction than the second portion 56, and therefore forms a groove on either side of the second portion 56. The aperture 58 communicates with the second portion 56 of the engaging recess 50.

The attachment system further includes a clamping member 60. The clamping member 60 is shown in Figures 3 to 8.

5 The clamping member 60 is of complementary cross sectional shape to the second portion 56 of the engaging recess 50 and has a first side 64 which is arranged to locate adjacent the lug 22 and a second side 66 opposite the first side 64. The second side 66 is arranged to locate adjacent the rectangular slot 57. The clamping member 60 further includes side surfaces 67 and a top surface 68.

10 The clamping member 60 includes a substantially cylindrical lug engaging member 62. The lug engaging member 62 is arranged to slide from a first position where it is substantially contained within a chamber 80 within the clamping member 60 to a second position where the lug engaging member 62 extends from the first side 64 of the clamping member 60.

15 The chamber 80 extends within the clamping member 60 from the first side 64 to a rear wall 82. The chamber 80 is substantially cylindrical in shape, and is complementary in shape to the lug engaging member 62.

A resilient annular member such as an O-ring 65 is located within a groove about the chamber 80 adjacent the first side 64 of the clamping member 60.

20 A substantially cylindrical slot 110 extends from the chamber 80 adjacent a rear end of the lug engaging member 62 to the second side 66 of the clamping member 60. The slot 110 is internally threaded.

The attachment system further includes a stabilizing member 98. The stabilizing member 98 is in the form of a prism, having front and rear faces 100, 102. The stabilizing member 98 is substantially the same shape as the rectangular slot 57.

The stabilizing member 98 has a substantially cylindrical aperture 112 which is arranged to locate, in use, adjacent the slot 110 of the clamping member 60 so as to form a single cylindrical passageway.

5 A forcing member in the form of a substantially cylindrical bolt 114 is arranged, in use, to locate within the passageway formed by the slot 110 and the aperture 112. The bolt is externally threaded, and is arranged to engage with the internally threaded slot 110. The bolt acts to hold the stabilizing member 98 relative to the clamping member 60 during use.

10 The use of the clamping member 60 and stabilizing member 98 will now be described, with reference to Figures 4 to 8.

The attachment portion 42 is positioned over the lip plate 12 with the lug 22 located within the first portion 54 of the engaging recess 50.

15 The clamping member 60 is then introduced through the rear aperture 52 and slid forward relative to the attachment portion 42 such that the first side 64 is adjacent the rear face 30 of the lug 22, and the clamping member 60 is free of the rectangular slot 57.

20 The stabilizing member 98 is then introduced into the aperture 58, and positioned in the rectangular slot 57 between the second side 66 of the clamping member 60 and the rear aperture 52. The presence of the stabilizing member 98 in the slot 57 prevents the movement of the clamping member 60 in the longitudinal direction.

The clamping member is activated as follows. The bolt 114 is introduced into the passage created by the slot 110 and the aperture 112, and is threadedly engaged with the slot 110. When the bolt 114 is fully within this passage, the end of the bolt 114 is

adjacent the lug engaging member 62..The application of a turning force to the bolt so as to promote the further advance of the bolt into the chamber 80 provides a pressing force on the lug engaging member 62.

The effect of the pressure in the chamber 80 is to force the lug engaging member 62 from its first position to its second position, whereby it engages the rear face 30 of the lug 22. In this way a compressive force is applied between the lug 22 and the stabilizing member 98, and therefore the attachment portion 42, thus locking the ground engaging tool 10 in position relative to the lip plate 12.

When it is desired to remove the ground engaging tool 10 from the lip portion 12, the bolt 114 is unscrewed from the slot 110, thus releasing pressure from the lug engaging portion 62. The attachment portion 42 can then be readily removed from the lip portion 12 in the reverse of the above process, potentially allowing some members to be reused.

Modifications and variations as would be apparent to a skilled addressee are deemed to be within the scope of the present invention.
